

# <div>

## Team 3

### History

This tag is created along with css as an alternative instead of <table> when non-linear content is desired. Years ago, divisions were sometimes called "layers." That term was because Netscape 4.0 introduced a tag called <layer> (a tag that was not part of any W3C recommendations) that played a similar role to the <div> tag.

### Concept

The <div> boxes in HTML 4, is the main element for web page structures, it is also possible to create rectangular display areas, to be identified exclusively in the code, the "id" attribute is used.

.

### Difference Between Div and Frame

#### <div>

It is used for grouping the Content as a BLOCKS

Web developers use <div> elements to group together HTML elements and apply CSS styles to many elements at once. For instance, by wrapping a set of paragraph elements into a <div> element, the developer can take advantage of CSS styles and apply a font to all paragraphs at once by applying a font style to the <div> tag instead of coding the same style for each paragraph element.

#### <frame>

Frames allow for multiple .html documents to be displayed inside of one browser window at a time. This means that one page has no content on it, but rather tells the browser which web pages you would like to open.

### Usability

The <div> tag is used to define a section within the document; It is commonly used to group a block of elements, to later add a certain style to it, and even to perform operations on that specific block.
